Abstract

There have been investigations into type-theoretic foundations for metaprogramming, notably Davies and Pfenning’s (2001) treatment in **S4** modal logic, where code evaluating to values of type A is given the modal type **Code** A ($\Box A$ in the original paper). Recently Kavvos (2017) extended PCF with **Code** A and intensional recursion, understood as the deductive form of the **GL** (Gödel-Löb) axiom in provability logic, but the resulting type system is logically inconsistent. Inspired by staged computation, we observe that a term of type **Code** A is, in general, code to be evaluated in a next stage, whereas **S4** modal type theory is a special case where code can be evaluated in the current stage, and the two types of code should be discriminated. Consequently, we use two separate modalities \Box and \Box' to model **S4** and **GL** respectively in a unified categorical framework while retaining logical consistency. Following Kavvos’ (2017) novel approach to the semantics of intensionality, we interpret the two modalities in the \mathcal{P} -category of assemblies and trackable maps. For the **GL** modality \Box' in particular, we use guarded type theory to articulate what it means by a ‘next’ stage and to model intensional recursion by guarded recursion together with Kleene’s second recursion theorem. Besides validating the **S4** and **GL** axioms, our model better captures the essence of intensionality by refuting congruence, i.e. two extensionally equal terms may not be intensionally equal, and the internal generic quoting $A \rightarrow \Box A$ as well as $A \rightarrow \Box' A$. Our results are developed in (guarded) homotopy type theory and formalised in Agda.

Keywords and phrases provability, guarded recursion, realisability, modal type, metaprogramming

Digital Object Identifier 10.4230/LIPIcs.CIT.2016.23

Supplementary Material The results were formalised in Agda 2.6.2 in the guarded cubical mode, and the source code is available at <https://github.com/L-TChen/provability>.

Funding This work was supported by the Ministry of Science and Technology of Taiwan under grant MOST 109-2222-E-001-002-MY3.

Acknowledgements We are grateful to Alex Kavvos and Tsung-Ju Chiang for insightful discussions. Also we would like to thank Rasmus Ejlers Møgelberg, Churn-Jung Liao, Ren-June Wang, Tom de Jong, Chad Nester, and Andrea Vezzosi for useful exchanges.

1 Introduction

Metaprogramming is the activity of writing metaprograms that manipulate program code. Executing a metaprogram can result in another program to be executed, and these successive executions are abstractly referred to as computation *stages*. A particular form of metaprogramming is *staged computation*, where fragments of a program are *internally* marked to be evaluated in multiple stages, so that the program can be partially evaluated to produce more efficient code. The stratification of computation stages forms possible worlds and can be ideally reasoned about by modal logic. Therefore, there have been investigations into type-theoretic foundations for staged computation with modalities [7, 8, 13, 20], which have influenced the design of practical implementations [16, 25, 26] to varying degrees.

Let `Code` A denote the type of code that evaluates to values of type A in a next stage. In Davies and Pfenning’s analysis of staged computation [8], `Code` corresponds to the **S4** modality \Box . More specifically, the **4** axiom $\Box A \rightarrow \Box \Box A$ corresponds to the use of code in the stage after the next, so code can be shared across all stages; the **T** axiom $\Box A \rightarrow A$ corresponds to the *evaluation* of code to its value in the same stage. For instance, in λ -calculus, it is well-known [4] that there are terms encoding Gödel code of a code and evaluating a code respectively.

Recently, Kavvos proposed *intensional recursion* [13] for `Code` to construct a value recursively from its own code (intension), extending the capabilities of metaprogramming. Logically, intensional recursion amounts to the **GL** (Gödel-Löb) axiom $\Box(\Box A \rightarrow A) \rightarrow \Box A$, where \Box stands for ‘provability’, and computationally its behaviour mirrors Kleene’s second recursion theorem. In contrast to general recursion $(A \rightarrow A) \rightarrow A$, which constructs a value recursively from its value (extension), intensional recursion alone does not lead to logical inconsistency. Kavvos explored the computational capabilities of a variant of PCF extended with `Code` viewed as both **S4** and **GL** modalities. Unfortunately, when `Code` is designed in this way, the type system is inconsistent so that it cannot be treated as a logical foundation.

To make **S4** and **GL** coexist in a single system while maintaining logical consistency, our approach is to keep the two modalities \Box and \square separate. Intuitively, while both modalities model code and appear similar, there are crucial differences: In general, programs are to be evaluated in a *next* stage, but **S4** is a special case where next stages include the current one, so the result of evaluating a program can be immediately used in the current stage, as witnessed by **T**. On the other hand, a program constructed with **GL** can recursively refer to its own code, which must not be evaluated within the same stage or risk non-termination computationally and inconsistency logically, so stage distinction has to be kept for **GL**.

To illuminate the difference, we present in this paper a denotational semantics of two types of code—a type $\Box A$ of code that can be evaluated in the current stage and a type $\square A$ of code to be evaluated in a next stage. To distinguish between intensions and extensions, we build upon the previous work using \mathcal{P} -categories [6, 14], which have an additional partial equivalence relation on morphisms that models extensional equality, while the underlying equality on morphisms models intensional equality. We revisit elements of realisability and construct a \mathcal{P} -category of assemblies on λ -calculus. Roughly speaking, an assembly X on λ -calculus is a set $|X|$ of extensions associated with at least an intension in the form of a λ -term (the existence of such an intension is merely a property that holds for the extension), while trackable maps are pairs of a function and one of its intensions, and can be equipped with both extensional and intensional equalities (taking only the function part or both parts into account). The denotations $\Box X$ and $\square X$ of the two types of code both consist of pairs (M, x) of an extension x and an associated λ -term M whose associated intensions are λ -terms that are reducible to the Gödel code $\ulcorner M \urcorner$. The choice of using $\ulcorner M \urcorner$ (rather than M as chosen by Kavvos [14]) as the intensions of (M, x) prevents $X \rightarrow \Box X$ from having the meaning of generic quoting. The difference between $\Box X$ and $\square X$ is what extensions are.

- For $\Box X$, the extension part x in (M, x) coincides with the values of the set $|X|$. We can then validate the **S4** axioms, for example $\Box X \rightarrow X$ (natural in X) by just projection.
- For $\square X$, the extension x does not come from $|X|$ but a different set $\triangleright |X|$ whose elements denote values of $|X|$ that are available in a next, or *later*, stage. This set $\triangleright |X|$ can be expressed directly in a *guarded type theory* which features Nakano’s later modality \triangleright and *guarded recursion* [19]. By working in guarded type theory, $\square X \rightarrow X$ can no longer be validated by projection (because x from (M, x) is available later rather than now) and is actually not possible; also intensional recursion can be modelled by guarded recursion.

The above constructions do not give rise to \mathcal{P} -functors but ‘exposures’ [14] so that congruence (the preservation of extensional equality) is not required by definition and is actually false. Hence, by refuting both congruence and generic quoting, which previous work [10, 14] did not achieve, our denotational semantics is more intensional in the sense that it provides a finer-grained equality which allows us to distinguish computationally equivalent intensions.

We use homotopy type theory (HoTT) [27] as our metalanguage, although this is mainly for convenience. More specifically, our work is built upon the reformulated set theory and logic within HoTT, which enable us to be precise about notions such as sets and propositions, and existence with explicit witnesses versus ‘mere’ existence (for example, within HoTT we can easily distinguish between ‘pairs of an extension and an intension’ and ‘extensions associated with at least an intension’). Moreover, implementations of HoTT are readily available, so we are able to formalise and verify our constructions, for which HoTT provides essential features that some other type theories lack, notably function extensionality: $(\forall (x : A). f x =_B g x) \rightarrow f = g$. Indeed, our work has been formalised in Agda 2.6.2 [9] which also supports guarded type theory in the guarded cubical mode.

Plan of the paper

After recalling preliminaries on homotopy type theory, untyped λ -calculus, and \mathcal{P} -categories in Section 2, we present the \mathcal{P} -category of assemblies on λ -calculus and trackable maps developed in HoTT in Section 3 and the denotational semantics of $\boxtimes A$ and $\boxdot A$ in Section 4, and discuss related work in Section 5 and future work in Section 6.

2 Preliminaries

Most, if not all, of the materials in this section are standard, so we do not go into the details.

2.1 Homotopy type theory

In type theory, between every two inhabitants x and y of a type A , there is a type $x =_A y$ of proofs that x and y are equal; given an equality proof $p : x =_A y$, any $z : B(x)$ can be converted to $\text{transport}(p, z) : B(y)$. Between equality proofs $p, q : x =_A y$ there is again a higher-dimensional equality type $p =_{x=A y} q$, and so on. Homotopy type theory (HoTT) identifies this infinite-dimensional structure of equality types as an abstract form of homotopy theory, where types are interpreted as spaces and equality proofs as paths; in particular, equality types are path spaces, and paths between paths are homotopies. We do not make use of the full generality of HoTT, however, and work exclusively with *propositions* and *sets*, whose equality structure degenerates at higher dimensions.

A *proposition* P is a type whose equality types $x =_P y$, for x and $y : P$, are all inhabited—all inhabitants of P are deemed equal, so all we care about P is whether it is inhabited, not its specific inhabitants. Hence, we will simply write \star when referring to an inhabitant of any proposition. If P and Q are propositions, then their product $P \times Q$ is also a proposition. Similarly, if a family $R(x)$ of types indexed by $x : A$ (where A is any type) are all propositions, then the product $\prod_{(x:A)} R(x)$ is also a proposition. Logically these give us conjunction and universal quantification; therefore we sometimes write $\forall (x : A). R(x)$ in place of $\prod_{(x:A)} R(x)$. Function types $A \rightarrow P$ are a special case of \prod , so we have implication too. On the other hand, the disjoint sums $P + Q$ and $\sum_{(x:A)} R(x)$ are usually not propositions. This reflects the fact that they are constructive disjunction and existential quantification. In particular, from a proof of $\sum_{(x:A)} R(x)$ we can project a witness $x : A$ and a proof of $R(x)$.

For any type A , the *propositional truncation* of A is a type $\|A\|$ for which there is an introduction rule that wraps any $a : A$ into $|a| : \|A\|$, and a higher one that introduces an inhabitant of $|a| =_{\|A\|} |b|$ for any $a, b : A$, equating all inhabitants of $\|A\|$ and making $\|A\|$ a proposition; its recursion principle maps $\|A\|$ to a proposition P provided that $A \rightarrow P$. With truncation, we can obtain a classical version of existential quantification by defining $\exists(x : A). R(x) := \left\| \sum_{(x:A)} R(x) \right\|$, from which we can no longer project a witness x and a proof of $R(x)$, but can only derive another proposition P provided that $\left(\sum_{(x:A)} R(x) \right) \rightarrow P$. Following the HoTT convention, if an existential quantification in an informal statement is truncated, we will use the words ‘mere’ or ‘merely’ to make it clear.

Sets are types whose equality types are all propositions, so for any two inhabitants of a set, there is at most one way for them to be equal. It is easy to check that the types we work with in this paper are sets: types constructed from sets and the type formers \times , $+$, \rightarrow , \prod , and \sum are all sets, and *Hedberg’s theorem* says that if a type A has decidable equality—that is, $\prod_{(x,y:A)} (x =_A y) + \neg(x =_A y)$ —then A is a set (which we will write as $A : \mathbf{Set}$ for short).

2.2 λ -calculus, Gödel encoding, and the second recursion theorem

For λ -calculus we only fix notations. The details are left to, for example, the classic textbook by Barendregt [4]. Terms are defined informally by

$$M ::= \mathbf{x} \mid MN \mid \lambda \mathbf{x}. M$$

where variables \mathbf{x} ’s are in the typewriter font. Λ denotes the type of terms and Λ_n the type of terms with at most n free variables. In particular, Λ_0 is the type of *closed terms*. Our formalisation uses the de Bruijn representation, so the α -equivalence $=_\alpha$ coincides with the identity type $=_\Lambda$ by construction. For the presentation in this paper, the variable with index i is written \mathbf{x}_i , and given $F : \Lambda_{n+1}$ we write $F[M]$ instead of $F[M/\mathbf{x}_0]$ for the substitution for the first free variable \mathbf{x}_0 . The type $M \rightarrow_\beta N$ of reductions from M to N consists of sequences of reduction rules such as $\beta : (\lambda \mathbf{x}. M) N \rightarrow_\beta M[N/\mathbf{x}]$; as a special case, the type $M \rightarrow_\beta M$ has exactly one inhabitant $\text{refl}_\rightarrow M$, or just refl_\rightarrow , which can be understood as either the empty sequence or (the proof of) the reflexivity of reduction. The types Λ and $M \rightarrow_\beta N$ have decidable equality, so they are sets by Hedberg’s theorem.

There is a function between λ -terms $\ulcorner \cdot \urcorner : \Lambda \rightarrow \Lambda_0$ such that $\ulcorner M \urcorner$ is normal and $M =_\alpha N$ whenever $\ulcorner M \urcorner =_\alpha \ulcorner N \urcorner$. Moreover, there are $\mathbf{ap}, \mathbf{subst} \in \Lambda_2$ and $\mathbf{quote}, \mathbf{eval} \in \Lambda_1$ satisfying

$$\begin{array}{ll} \mathbf{ap}[\ulcorner M \urcorner][\ulcorner N \urcorner] \rightarrow_\beta \ulcorner MN \urcorner & \mathbf{subst}[\ulcorner F \urcorner][\ulcorner N \urcorner] \rightarrow_\beta \ulcorner F[N] \urcorner \\ \mathbf{quote}[\ulcorner M \urcorner] \rightarrow_\beta \ulcorner \ulcorner M \urcorner \urcorner & \mathbf{eval}[\ulcorner M \urcorner] \rightarrow_\beta M. \end{array}$$

This function $\ulcorner \cdot \urcorner$ is called a *Gödel encoding*. Traditionally, a quoted term $\ulcorner M \urcorner$ is called a Gödel *number* since the encoding $\ulcorner \cdot \urcorner$ assigns to every term M a Church numeral $\mathbf{c}_{\#M}$. An encoding needs not be a number at all, however, so we simply call $\ulcorner M \urcorner$ a *code* of M rather than a number. For details on the axiomatic characterisation of encoding, see Polonsky [22].

Note that the term \mathbf{quote} can only compute the code of a term $\ulcorner M \urcorner$ which is already in quoted form. Indeed, no term can compute the code of any arbitrary closed term.

► **Proposition 2.1.** *There is no $Q : \Lambda_1$ such that $Q[M] \rightarrow_\beta \ulcorner M \urcorner$ for all $M : \Lambda_0$.*

Contrary to the well-known first recursion theorem, Kleene’s second recursion theorem works for *code* instead of values and will be used to model the **GL** modality.

► **Theorem 2.2 (SRT).** *For every $F : \Lambda_n$ there exists $M : \Lambda_n$ such that $M \rightarrow_\beta F \ulcorner M \urcorner$.*

2.3 \mathcal{P} -Categories and exposures

Instead of ordinary categories, we work with \mathcal{P} -categories pioneered by Čubrić et al. [6], where morphisms are equipped with an additional partial equivalence relation (PER) as another level of equality between morphisms. Kavvos [14] recently advocated its use and introduced a construct called *exposure*, which is similar to a (\mathcal{P} -)functor but does not enforce the preservation of PERs of \mathcal{P} -categories, to manifest the essence of intensionality.

► **Definition 2.3.** A *partial equivalence relation* is a symmetric and transitive relation. A \mathcal{P} -set (X, \sim_X) is a set X with a partial equivalence relation \sim_X . A \mathcal{P} -function from (X, \sim_X) to (Y, \sim_Y) is a function $f: X \rightarrow Y$ which respects the relation \sim in the sense that $f x \sim_Y f y$ whenever $x \sim_X y$. An element $x \in X$ is *well-defined* (with respect to \sim) if $x \sim x$.

The identity function id_X is a \mathcal{P} -function, and the composite of two \mathcal{P} -functions is again a \mathcal{P} -function. It turns out that \mathcal{P} -sets and \mathcal{P} -functions form a cartesian closed category, so by enriched category theory [15] we have a notion of categories enriched by \mathcal{P} -sets below.

► **Definition 2.4** ([6, Definition 2.4]). A \mathcal{P} -category is a category whose hom-sets are \mathcal{P} -sets satisfying the associativity and identity laws up to \sim in the sense that

- (i) every object X has an identity morphism id_X ,
- (ii) $g \circ f \sim g' \circ f'$ whenever $g \sim g'$ and $f \sim f'$,
- (iii) $\text{id} \circ f \sim f'$ and $f \circ \text{id} \sim f'$ whenever $f \sim f'$,
- (iv) $h \circ (g \circ f) \sim (h' \circ g') \circ f'$ whenever $h \sim h'$, $g \sim g'$, and $f \sim f'$.

A \mathcal{P} -category has two kinds of equality for morphisms—the underlying identity $=$ and the partial equivalence relation \sim , where the former can be used to model the *intensional equality* and the latter the *extensional equality* akin to the structure of multiple judgemental equalities in the modal type theory by Pfenning [21]. Having two different equalities $=$ and \sim reflects the fact that, for example, α -equivalent terms are β -equivalent but not vice versa. For categorical semantics, where terms are interpreted as morphisms, an interpretation into a \mathcal{P} -category is able to discriminate these two kinds of equality, enabling us to model intensionality. The usual categorical notions such as functors and initiality are up to the intensional equality $=$; when we want to use the notions up to the extensional equality \sim , we will add the ' \mathcal{P} -' prefix and say \mathcal{P} -functors, \mathcal{P} -initiality, etc.

We recall the notion of exposures, which are like \mathcal{P} -functors but are intended to 'expose' intensional differences at the extensional level: if an exposure is applied to intensionally different morphisms (which may or may not be identified extensionally), the resulting morphisms may be distinguished extensionally. Consequently, exposures are not required to preserve the extensional equality. Moreover, exposures are only supposed to refine the extensional equality and do not eliminate existing extensional differences—that is, they are faithful with respect to \sim . The precise definition is as follows.

► **Definition 2.5.** Given \mathcal{P} -categories \mathbf{C} and \mathbf{D} , an *exposure* $Q: \mathbf{C} \rightarrow \mathbf{D}$ consists of (a) a mapping Q from objects X of \mathbf{C} to objects QX of \mathbf{D} and (b) from well-defined morphisms $f: X \rightarrow Y$ to well-defined morphisms $Qf: QX \rightarrow QY$ satisfying the following properties:

- (i) $Q\text{id}_X \sim \text{id}_{QX}$,
- (ii) $Q(g \circ f) \sim Qg \circ Qf$, and
- (iii) $f \sim g$ whenever $Qf \sim Qg$ for any two well-defined morphisms $f, g: X \rightarrow Y$.

The *identity exposure* \mathcal{I} maps every object or morphism to itself. Composing two exposures in the usual way clearly gives us an exposure.

Similarly, the notion of natural transformations is introduced for exposures, sharing the same idea with ordinary natural transformations but only up to \sim .

► **Definition 2.6.** Given exposures $P, Q: \mathbf{C} \multimap \mathbf{D}$, a *natural transformation of exposures* $t: P \rightarrow Q$ is a family of well-defined morphisms $t_X: PX \rightarrow QX$ such that $Qf \circ t_X \sim t_Y \circ Pf$ for every well-defined morphism $f: X \rightarrow Y$.

An *evaluator* for an endo-exposure Q is a natural transformation from Q to \mathcal{I} .

To model the **S4** modality, we may further define *comonadic exposures* introduced by Kavvos [14] as an endo-exposure equipped with an evaluator and a natural transformation δ from Q to Q^2 subject to comonad laws. In the presence of intensionality, however, we observe that the naturality is not always appropriate. We will revisit this issue in Section 4.

3 \mathcal{P} -Category of assemblies on λ -calculus

Assemblies are used to accommodate the information of how extensions are *realised by* intensions. Accordingly an appropriate notion of morphisms between assemblies is introduced to form a \mathcal{P} -category, laying the technical foundation for Section 4.

3.1 Assembly and trackable map

Traditionally, an assembly on natural numbers is a set $|X|$ with a realisability relation $\Vdash \subseteq \mathbb{N} \times |X|$ such that for every x in $|X|$ there exists some a with $a \Vdash x$, where a is said to *realise* x or a is a *realiser* of x . The modern notion of assemblies [28] is often defined on a partial combinatory algebra (A, \cdot) , called *PCA* for short, where \cdot is a partial binary operation. For the sake of formalisation and potential applications in programming language design, we base our definition on λ -calculus subject to α -equivalence, which is more akin to the one based on an ordered PCA [12].

► **Definition 3.1.** An *assembly* X on λ -calculus consists of a *carrier set* $|X| : \mathbf{Set}$ and a family \Vdash_X of sets indexed by Λ_0 and $|X|$ as its *realisability relation* such that (a) there is merely a realiser $M : \Lambda_0$ of every $x : |X|$, and (b) $M \Vdash_X x$ whenever $M \longrightarrow_\beta N$ and $N \Vdash_X x$. In other words, an assembly is a quadruple $(|X|, \Vdash_X, r_X, t_X)$ of type

$$\mathbf{Asm}_0 \equiv \sum_{(|X| : \mathbf{Set})} \sum_{(\Vdash_X : \Lambda_0 \rightarrow |X| \rightarrow \mathbf{Set})} \mathbf{Respects}(\Vdash_X, \longrightarrow_\beta) \times \mathbf{RightTotal}(\Vdash_X)$$

where

$$\mathbf{Respects}(\Vdash_X, \longrightarrow_\beta) \equiv \prod_{(MN : \Lambda_0)} \prod_{(x : |X|)} (M \longrightarrow_\beta N) \rightarrow (N \Vdash x) \rightarrow (M \Vdash x) \quad (3.1)$$

$$\mathbf{RightTotal}(\Vdash_X) \equiv \forall (x : |X|). \exists (M : \Lambda_0). M \Vdash x \quad (3.2)$$

Our type-theoretic formulation is almost a direct translation from the set-theoretic formulation except that the realisability relation \Vdash is not really a relation but an indexed family of sets. As we would like to account for intensional equality in addition to extensional equality between terms, computationally equivalent terms should not be identified *a priori*. It turns out that formulating the interaction with reduction \longrightarrow_β as (3.1) in line with the definition on an ordered PCA suffices to derive familiar properties.

► **Example 3.2.** The type Λ_0 of closed terms with the reduction relation \longrightarrow_β as its realisability relation is an assembly $(\Lambda_0, \longrightarrow_\beta, r_{\Lambda_0}, t_{\Lambda_0})$ where r_{Λ_0} and t_{Λ_0} are given by the transitivity and the reflexivity of \longrightarrow_β .

► **Example 3.3.** Every natural number $n : \mathbb{N}$ is realised by terms reducible to its Church numeral c_n . That is, the type \mathbb{N} of natural numbers with $M \Vdash_{\mathbb{N}} n$ whenever $M \longrightarrow_{\beta} c_n$ is an assembly where $r_{\mathbb{N}}$ and $t_{\mathbb{N}}$ are given by the transitivity and the reflexivity of \longrightarrow_{β} .

A morphism between assemblies on a PCA (A, \cdot) is defined as a function f merely *tracked* by some $b \in A$ in the sense that there merely exists some b such that $b \cdot a \Vdash f x$ whenever $a \Vdash x$. In this case, b is called the *tracker* of f . It is noted by Kavvos [14] that to bring out intensionality the tracker should be considered as part of the structure instead of a property.

► **Definition 3.4.** Given assemblies X and Y , a *trackable map* f from X to Y consists of a function $|f| : |X| \rightarrow |Y|$ and a term $F : \Lambda_1$ such that $F[M] \Vdash |f| x$ whenever $M \Vdash x$. That is, the type $\text{Asm}_1(X, Y)$ of trackable maps is $\sum_{(|f| : |X| \rightarrow |Y|)} \sum_{(F : \Lambda_1)} \text{Tracks}_{X,Y}(F, |f|)$ where

$$\text{Tracks}_{X,Y}(F, |f|) := \prod_{(M : \Lambda_0)} \prod_{(x : |X|)} (M \Vdash_X x) \rightarrow (F[M] \Vdash_Y |f| x).$$

A *merely trackable map* is an inhabitant of $\sum_{(|f| : |X| \rightarrow |Y|)} \exists (F : \Lambda_1). \text{Tracks}_{X,Y}(F, |f|)$.

By definition, a trackable map $f \equiv (f, F, \mathfrak{f})$ consists of not only a function $|f|$ between carriers but also its tracker F and a transformation \mathfrak{f} of realisability.

► **Example 3.5.** Every assembly X has an identity map $id_X := (id_{|X|}, \mathfrak{x}_0, \text{pr}_3)$ where

$$\text{pr}_3 := \lambda M. \lambda x. \lambda r. r : \prod_{(M : \Lambda_0)} \prod_{(x : |X|)} (M \Vdash_X x) \rightarrow (M \Vdash_X x)$$

since $\mathfrak{x}_0[M]$ is judgementally equal to M .

Now we proceed with defining the composition of trackable maps. Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be trackable maps. Then, the term substitution $(G, F) \mapsto G[F]$ can be thought of as (intensional) function composition, since $G[F[M]] =_{\Lambda_0} G[F][M]$ holds for any term M . Given any $r : M \Vdash_X x$, the inhabitant $\mathfrak{g}(\mathfrak{f}r)$ has type $G[F[M]]$ and its transportation along a witness $p : G[F[M]] =_{\Lambda_0} G[F][M]$ has type $G[F][M]$, defining a function $\lambda M x r. \text{transport}(p, \mathfrak{g}(\mathfrak{f}r))$. The above discussion amounts to defining a composition operation $(g, f) \mapsto g \circ f$.

3.2 Extensional equality and \mathcal{P} -category of assemblies

We define the partial equivalence relation \sim , referred to as the extensional equality, on trackable maps by $f_1 \sim f_2$ (f_1 is *extensionally equal* to f_2) if $|f_1| = |f_2|$.

► **Proposition 3.6.** The type Asm_0 of assemblies and the family of types $\text{Asm}_1(X, Y)$ for any two assemblies X and Y with the extensional equality form a \mathcal{P} -category $\text{Asm}(\Lambda)$.

We now investigate some of its basic properties.

► **Example 3.7** (\mathcal{P} -Terminal object). The unit $\top := (\mathbf{1}, \Vdash_{\top}, r_{\top}, t_{\top})$ is \mathcal{P} -terminal where

- (i) $\mathbf{1}$ is the unit type,
- (ii) \Vdash_{\top} a relation defined by $M \Vdash_{\top} \star := M \longrightarrow_{\beta} \mathbf{I}$ where $\mathbf{I} := \lambda x. x$,
- (iii) $r_{\top} : (M \longrightarrow_{\beta} N) \rightarrow (N \longrightarrow_{\beta} L) \rightarrow (M \longrightarrow_{\beta} L)$ given by the transitivity of \longrightarrow_{β} ,
- (iv) and t_{\top} the fact that the only inhabitant $\star : \mathbf{1}$ has a realiser \mathbf{I} (by reflexivity).

The finality follows from function extensionality.

The construction of binary \mathcal{P} -products is also typical—the carrier of a product is the cartesian product and a pair (x, y) is realised by M if its Church-encoded projections realise x and y . It follows that $\mathbf{Asm}(\Lambda)$ has finite \mathcal{P} -products.

Every inhabitant of an assembly X corresponds to a merely trackable map to X from the terminal object \top , which are called (*global*) *elements* of X , and distinct merely trackable maps can be separated by elements of X . In $\mathbf{Asm}(\Lambda)$, as trackers are part of trackable maps, an element has to be constructed with an intension.

► **Lemma 3.8.** *Let X be an assembly. Then the following statements hold:*

1. *Every inhabitant $x : |X|$ corresponds to a merely trackable map from \top to X .*
2. *Every pair of $x : |X|$ and $M : \Lambda_0$ with $r : M \Vdash_X x$ defines a closed element of X , i.e. a trackable map $(\lambda _ . x, M, \lambda _ . \lambda _ . r)$ from \top to X .*

As expected, the \mathcal{P} -terminal object \top in $\mathbf{Asm}(\Lambda)$ is a \mathcal{P} -separator in the sense that for any two trackable maps f_1 and f_2 we have $f_1 \sim f_2$ if $f_1 \circ x \sim f_2 \circ x$ for every element x of X . Even further, we can restrict to closed elements.

► **Proposition 3.9.** *Two trackable maps $f_1, f_2 : X \rightarrow Y$ are extensionally equal if and only if $f_1 \circ x \sim f_2 \circ x$ for every closed element $x : \top \rightarrow X$. In particular, the \mathcal{P} -terminal object \top is a \mathcal{P} -separator in $\mathbf{Asm}(\Lambda)$.*

Proof sketch. The proof from left to right is trivial. For the proof from right to left, let f_1 and f_2 be two trackable maps. By function extensionality, to prove that $|f_1| = |f_2|$, we define for any inhabitant $x : |X|$ a closed element \hat{x} of X constructed by Lemma 3.8 using M_x and $r : M_x \Vdash x$ given by the right totality t_X . By the recursion principle of propositional truncation and $|Y|$ being a set, it follows from our assumption that there exists a path $|f_1| x = |f_2| x$ independent of the choice of M_x and \mathfrak{M}_x . ◀

► **Example 3.10 (Initial object).** The empty assembly \perp is \mathcal{P} -initial consisting of the empty type $\mathbf{0}$ and a relation $\Vdash_\perp : \Lambda_0 \rightarrow \mathbf{0} \rightarrow \mathbf{Set}$ given by the elimination rule for the empty type. The other two components r_\perp and t_\perp are trivial.

In addition, one can show that \perp is even a *strict* \mathcal{P} -initial object. That is,

► **Proposition 3.11.** *Any trackable map from some assembly X to \perp is a \mathcal{P} -isomorphism.*

From the strictness of the initial object, no morphism from \top to \perp could exist.

The construction of \mathcal{P} -exponential $X \Rightarrow Y$ is a bit laborious and, perhaps surprisingly, $X \Rightarrow Y$ has the type of *merely* trackable maps as its carrier.

► **Example 3.12 (\mathcal{P} -Exponential).** Given assemblies X and Y , define

$$|X \Rightarrow Y| := \sum_{f : |X| \rightarrow |Y|} \exists (F : \Lambda_1). \text{Tracks}_{X,Y}(F, f) \equiv \sum_{f : |X| \rightarrow |Y|} \left\| \sum_{F : \Lambda_1} \text{Tracks}_{X,Y}(F, f) \right\|$$

with $L \Vdash_{X \Rightarrow Y} (f, \star) := \prod_{(M : \Lambda_0)} \prod_{(x : |X|)} (M \Vdash_X x) \rightarrow (LM \Vdash_Y f x)$.

It remains to construct $r_{X \Rightarrow Y}$ and $t_{X \Rightarrow Y}$: We know that $L' \twoheadrightarrow_\beta L$ implies $L' M \twoheadrightarrow_\beta LM$, so L' realises (f, \star) whenever L realises (f, \star) and $L' \twoheadrightarrow_\beta L$ by r_Y . For every $(f, \star) : |X \Rightarrow Y|$, there merely exists a tracker of f , say F . We see that $L := (\lambda x. F)$ realises (f, \star) , since $(\lambda x. F) M \twoheadrightarrow_\beta F[M]$ for any M and $F[M] \Vdash_Y f x$ whenever $M \Vdash_X x$. By applying the recursion principle of the truncated type $\left\| \sum_{(F : \Lambda_1)} \text{Tracks}_{X,Y}(F, f) \right\|$ to the second component of (f, \star) , there merely exists a realiser of (f, \star) for the right totality.

339 The *evaluation map* $(X \Rightarrow Y) \times X \xrightarrow{ev_{X,Y}} Y$ natural in X and Y consists of a function
 340 $((f, \star), x) \mapsto f x$ and its tracker $(\text{proj}_1 \mathbf{x}_0)(\text{proj}_2 \mathbf{x}_0) : \Lambda_1$ where \mathbf{x}_0 is the free variable
 341 (thought of as a pair of realisers for a function and its argument) and proj_i the projection
 342 function between λ -terms.

343 The *curried map* $(f^*, F^*, \mathfrak{f}^*)$ of a trackable function (f, F, \mathfrak{f}) from $Z \times X$ to Y consists of a
 344 function $f^* := \lambda z. ((\lambda x. f(z, x)), \star_z)$, where by the recursion principle on the mere existence
 345 of a realiser $L_z := t_Z z$ there is merely a tracker $F[\langle L_z, \mathbf{x}_0 \rangle]$ of $\lambda x. f(z, x)$, and a term
 346 $F^* := \lambda \mathbf{x}_0. F[\langle \mathbf{x}_1, \mathbf{x}_0 \rangle]$ with a witness \mathfrak{f}^* of $\prod_{(L:\Lambda_0)} \prod_{(z:|Z|)} (L \Vdash_Z z) \rightarrow (F^*[L] \Vdash_{X \Rightarrow Y} f z)$
 347 because of the reduction

$$348 \quad (\lambda \mathbf{x}_0. F[\langle L, \mathbf{x}_0 \rangle]) M \longrightarrow_\beta F[\langle L, M \rangle]$$

349 and that F is indeed a tracker of $f: |Z \times X| \rightarrow |Y|$. It is routine to verify remaining details.

350 ► **Corollary 3.13.** *$\text{Asm}(\Lambda)$ is a cartesian closed \mathcal{P} -category with a strict \mathcal{P} -initial object.*

351 4 Realisability semantics for two modalities

352 In this section, we introduce an exposure $\boxtimes: \text{Asm}(\Lambda) \nrightarrow \text{Asm}(\Lambda)$ modelling the **S4** modality
 353 and show that a generic quoting $X \rightarrow \boxtimes X$ cannot exist. Then, we move to guarded type
 354 theory as our metalanguage and introduce an exposure \square (in a staged setting) to model
 355 the **GL** modality. The construction refutes $X \rightarrow \square X$ by the same argument for \boxtimes and the
 356 reflection principle $\square X \rightarrow X$. Finally, we derive the **GL** axiom as well as its deductive form.

357 4.1 An exposure for the S4 modality

358 Given an assembly X , which describes a set of extensions merely realised by some intensions
 359 (i.e. terms), we can expose the intensions at the level of extensions by constructing an
 360 assembly $\boxtimes X$ where an inhabitant $(M, x, r) : |\boxtimes X|$ is an extension $x : |X|$ and a term
 361 $M : \Lambda_0$ that realises x , witnessed by $r : M \Vdash_X x$. This term M becomes the main part of
 362 the extension (with respect to $\boxtimes X$) and should be (merely) realised by some intensional
 363 representation of M ; a natural choice of such representation is $\ulcorner M \urcorner$, or indeed any term
 364 β -reducible to $\ulcorner M \urcorner$. In short, the carrier and the realisability relation of $\boxtimes X$ are defined as

$$365 \quad |\boxtimes X| := \sum_{(M:\Lambda_0)} \sum_{(x:|X|)} M \Vdash_X x \quad \text{and} \quad (N \Vdash_{\boxtimes X} (M, x, r)) := N \longrightarrow_\beta \ulcorner M \urcorner$$

366 respectively. It turns out that $\boxtimes X := (|\boxtimes X|, \Vdash_{\boxtimes X}, r_{\boxtimes X}, t_{\boxtimes X})$ is indeed an assembly where
 367 $r_{\boxtimes X}$ and $t_{\boxtimes X}$ are the transitivity and the reflexivity of \longrightarrow_β .

368 To make \boxtimes an exposure, we should also define the mapping on morphisms. Consider any
 369 trackable map f from X to Y and define $\boxtimes f := (|f|^\boxtimes, F^\boxtimes, \mathfrak{f}^\boxtimes): \boxtimes X \rightarrow \boxtimes Y$ as follows. First
 370 define a function from $|\boxtimes X|$ to $|\boxtimes Y|$ by

$$371 \quad |f|^\boxtimes: (M, x, r) \mapsto (F[M], |f| x, \mathfrak{f} M x r).$$

372 To give a tracker of f^\boxtimes , recall that there is a term **subst** performing term substitution on
 373 codes (Section 2.2), and then the term $F^\boxtimes := \text{subst} \ulcorner F \urcorner \mathbf{x}$ tracks f^\boxtimes because

$$374 \quad \text{subst} \ulcorner F \urcorner N \longrightarrow_\beta \text{subst} \ulcorner F \urcorner \ulcorner M \urcorner \longrightarrow_\beta \ulcorner F[M] \urcorner \Vdash_{\boxtimes Y} f^\boxtimes(M, x, r)$$

375 completing the definition of f^\boxtimes . In short, $\boxtimes f := (|f|^\boxtimes, F^\boxtimes, \mathfrak{f}^\boxtimes)$ is a trackable map.

377 ► **Definition 4.1.** By \star we denote a closed element of $\boxtimes \top$ given by Lemma 3.8 with
 378 $(\mathbf{I}, \star, \text{refl}_{\rightarrow}) : |\boxtimes \top|$ and its realiser $\ulcorner \mathbf{I} \urcorner$.

379 ► **Remark 4.2.** Given elements a, b of X with $a \sim b$ but with different trackers, it follows that
 380 by definition $\boxtimes a \circ \star \not\sim \boxtimes b \circ \star$ are two extensionally different elements. That is, \boxtimes does not
 381 preserve extensional equality.

382 The assembly $\boxtimes \top$ cannot be \mathcal{P} -isomorphic to \top , since there are countably many inhabit-
 383 ants of $|\boxtimes \top|$ while there is exactly one inhabitant of $|\top| \equiv \mathbf{1}$. Similarly, there are trackable
 384 maps from $\boxtimes(X \times Y)$ to $\boxtimes X \times \boxtimes Y$ and vice versa, but they are not \mathcal{P} -isomorphic. It follows
 385 that the exposure \boxtimes does not preserve finite \mathcal{P} -products.

386 ► **Theorem 4.3.** $\boxtimes : \text{Asm}(\Lambda) \rightleftarrows \text{Asm}(\Lambda)$ is an exposure of assemblies. Moreover, there is an
 387 evaluator ϵ for \boxtimes , i.e. a natural transformation ϵ from \boxtimes to \mathcal{I} .

388 **Proof sketch.** It is routine to prove the preservation of identities and composition. For
 389 example, it follows by definition that $\text{id}_{|\boxtimes X|}^\boxtimes(M, x, r) \equiv (\mathbf{x}[M], x, \text{pr}_3 M x r) \equiv (M, x, r)$.

390 Now we show that \boxtimes reflects the extensional equality. Let f and g be trackable maps
 391 from X to Y . By assumptions that $\boxtimes f \sim \boxtimes g$ and that there is merely $M : \Lambda_0$ with
 392 $r : M \Vdash_X x$, we can apply the recursion principle of propositional truncation to derive

$$393 \quad \boxtimes f(M, x, r) = (F[M], |f| x, \mathbf{f} M x r) = (G[M], |g| x, \mathbf{g} M x r) = \boxtimes g(M, x, r)$$

394 since the identity type on $\boxtimes Y$ is a proposition. Therefore, we have $\prod_{(x:|X|)} |f| x =_Y |g| x$.
 395 By function extensionality it then follows that $(|f| =_{|X| \rightarrow |Y|} |g|) \equiv f \sim g$.

396 As for the evaluator $\epsilon_X : \boxtimes X \rightarrow X$, recall the term **eval** which evaluates a code (Sec-
 397 tion 2.2). We simply define $|\epsilon_X|$ by $(M, x, r) \mapsto x$. Then, given $N : \Lambda_0$ with $N \twoheadrightarrow_\beta \ulcorner M \urcorner$,
 398 we have $\text{eval}[N] \twoheadrightarrow_\beta \text{eval}[\ulcorner M \urcorner] \twoheadrightarrow_\beta M$ where $M \Vdash_X x$ is witnessed by r . That is, $|\epsilon_X|$
 399 is tracked by **eval**. The naturality of ϵ follows by definition. ◀

400 Given an element a of X , define its *quotation* as the element $\boxtimes a \circ \star$ of $\boxtimes X$. The choice
 401 of \star does not matter if a is closed, since $\boxtimes a \circ \star' \sim \boxtimes a \circ \star$ for any element \star' of $\boxtimes \top$. We
 402 say that a trackable map $q : X \rightarrow \boxtimes X$ *quotes* an element a of X whenever $q \circ a \sim \boxtimes a \circ \star$.
 403 The (4) axiom can be realised by a family of trackable maps which quote closed elements:

404 ► **Proposition 4.4.** There is a family of functions $|\delta_X|(M, x, r) := (\ulcorner M \urcorner, (M, x, r), \text{refl}_{\rightarrow})$
 405 from $|\boxtimes X|$ to $|\boxtimes \boxtimes X|$ tracked by **quote** which quote closed elements of $\boxtimes X$.

406 The fact that δ_X quotes closed elements justifies the computational meaning categorically.
 407 Yet, δ_X may fail to quote an element a if a is not closed, since in general the intension part
 408 of $\boxtimes a$ is applied *verbatim*. That is, $|\boxtimes a|(\mathbf{I}, \star, \text{refl}_{\rightarrow})$ is $(F[\mathbf{I}], (M, x, r), s)$ where $F[\mathbf{I}]$ is
 409 not necessarily α -equivalent to $\ulcorner M \urcorner$. The subtlety goes on:

410 ► **Remark 4.5.** One may expect that $(\boxtimes, \epsilon, \delta)$ is comonadic in the sense that δ is a natural
 411 transformation up to \sim satisfying comonad laws, but these maps δ_X are *not* natural in X .
 412 In detail, for each trackable map $f : X \rightarrow Y$ the inhabitant

$$413 \quad \delta_Y(\boxtimes f(M, x, r)) \equiv (\ulcorner F[M] \urcorner, (F[M], f x, \mathbf{f} M x r), \text{refl}_{\rightarrow}) : \boxtimes \boxtimes Y$$

414 is not equal to

$$415 \quad \boxtimes \boxtimes f(\delta_X(M, x, r)) \equiv (\text{subst}^{\ulcorner F \urcorner \ulcorner M \urcorner}, (F[M], f x, \mathbf{f} M x r), \text{subst}_{\rightarrow}) : \boxtimes \boxtimes Y$$

416 despite that their extensions are the same, where $\text{subst}_{\rightarrow}$ is the witness of the reduction
 417 sequence $\text{subst}^{\ulcorner F \urcorner \ulcorner M \urcorner} \twoheadrightarrow_\beta \ulcorner F[M] \urcorner$. Let us define $(M, x, r) \leq (N, y, s)$ if $M \twoheadrightarrow_\beta N$ and
 418 $x = y$ and $f \leq g$ if $|f| x \leq |g| x$ for all x . Then we only have $|\boxtimes \boxtimes f \circ \delta_X| \leq |\delta_Y \circ \boxtimes f|$. In
 419 general, the *lax naturality* appears more appropriate in the presence of intensionality.

The normality condition is realised exactly by **ap** without naturality:

► **Proposition 4.6.** *There is a family of trackable maps from $\boxtimes(X \Rightarrow Y)$ to $\boxtimes X \Rightarrow \boxtimes Y$ tracked by $\lambda x_0. \mathbf{ap}[x_1] x_0$.*

On the other hand, it is impossible for the rule $A \rightarrow \boxtimes A$ to compute quotations for arbitrary A , since this is already impossible for the particular case of $\Lambda_0 \rightarrow \boxtimes \Lambda_0$.

► **Theorem 4.7.** *No trackable map from Λ_0 to $\boxtimes \Lambda_0$ quotes closed elements of Λ_0 .*

Proof. Assume $\eta: \Lambda_0 \rightarrow \boxtimes \Lambda_0$ with $\eta \circ a \sim \boxtimes a \circ \star$ for any $a: \top \rightarrow \Lambda_0$ given by Lemma 3.8. Every closed term M defines an element $\widehat{M} := (\lambda _ . M, M, \lambda _ . \lambda _ . \mathbf{refl}_{\rightarrow})$ of Λ_0 and thus $\left| \boxtimes \widehat{M} \right| (N, y, s) = (M, M, \mathbf{refl}_{\rightarrow})$ for any $(N, y, s): \boxtimes \top$ by definition. By assumption

$$|\eta| M \equiv |\eta| \left(\left| \widehat{M} \right| \star \right) = \left| \boxtimes \widehat{M} \right| (|\star| \star) = (M, M, \mathbf{refl}_{\rightarrow}),$$

so the tracker \mathbf{Q} of η should satisfy $\mathbf{Q}[N] \rightarrow_{\beta} \ulcorner M \urcorner$ whenever $N \rightarrow_{\beta} M$. In particular, it follows that $\mathbf{Q}[M] \rightarrow_{\beta} \ulcorner M \urcorner$. By Proposition 2.1 such \mathbf{Q} cannot exist. ◀

As the choice of \star does not matter for closed elements a , the above theorem shows that a very limited form of naturality for any two morphisms η_{Λ_0} and η_{\top} satisfying $\eta_{\Lambda_0} \circ a \sim \boxtimes a \circ \eta_{\top}$ for any closed a remains impossible. It is not clear how to state ‘parametricity’ for \boxtimes so that any family of morphisms from A to $\boxtimes A$, satisfying a reasonable naturality, can be rejected.

4.2 An exposure for the GL modality

Kavvos [14] advocated that the provability modality \Box and the **GL** axiom $\Box(\Box A \rightarrow A) \rightarrow \Box A$ can also be understood as the type of code of type A and as intensional recursion respectively from the computational perspective. Since we already have an exposure \boxtimes modelling typed code, a natural approach is to extend \boxtimes to model the **GL** axiom in addition to **S4**. However, it is known that the **GL** axiom is incompatible with the reflection principle $\Box A \rightarrow A$. Indeed, let A be the falsity \perp for both laws. Then, we have $\Box(\Box \perp \rightarrow \perp) \rightarrow \Box \perp$ and $\Box \perp \rightarrow \perp$. By the necessitation rule we can derive $\Box(\Box \perp \rightarrow \perp)$ and thus by modus ponens we can derive $\Box \perp$ and finally \perp . Therefore, by Proposition 3.11 and Theorem 4.3, we cannot expect the exposure \boxtimes to model the **GL** axiom if we want the type system to be logically consistent.

To untie the knot and retain consistency and the understanding of $\Box A$ as code of type A , we observe that in general $\Box A$ and $\boxtimes A$ are types for different kinds of code and should be kept separate: code constructed with intensional recursion can only be expanded in stages (or otherwise may result in non-termination), whereas code supporting **S4** is only a special case where next stages include the current one so that $\epsilon_X: \boxtimes X \rightarrow X$ is allowed. Therefore, separately from \boxtimes , we give an exposure $\Box: \mathbf{Asm}(\Lambda) \multimap \mathbf{Asm}(\Lambda)$ modelling the **GL** modality in a staged setting (Section 4.2.2). To express staged constructions more conveniently (without stage indexing), we work within guarded type theory.

4.2.1 Digression: Clocked cubical type theory

The particular version of guarded type theory we use is *clocked cubical type theory* (CCTT for short) [17], which is a metalanguage extending HoTT with a later modality \triangleright^{κ} parametrised by a ‘clock’ κ and guarded recursion. Here we only intuitively introduce the constructs and properties of CCTT that are necessary for the informal presentation of the constructions in Section 4.2.2, but the formal details are all checked in Agda.

23:12 Realising Intensional S4 and GL Modalities

CCTT features a new type $\triangleright(\alpha : \kappa). A$ of suspended computations that take in a tick α on a clock κ to produce an inhabitant of A in a next stage. (Clocks will be discussed towards the end and can be ignored for now.) An inhabitant of $\triangleright(\alpha : \kappa). A$ therefore resembles a function computationally, and can be introduced as a λ -expression $\lambda(\alpha : \kappa). t$ (often abbreviated to $\lambda\alpha. t$) where $t : A$, or eliminated by application to a tick, denoted by $f[\alpha] : A$ where $f : \triangleright(\alpha : \kappa). A$ and $\alpha : \kappa$. For brevity, $\triangleright(\alpha : \kappa). A$ is written as $\triangleright^\kappa A$ if α is not referred to in A . For example, the following term implements the normality axiom for \triangleright^κ :

$$\mathbf{ap}^\kappa \equiv \lambda f. \lambda x. \lambda \alpha. f[\alpha] (x[\alpha]) : \triangleright^\kappa (A \rightarrow B) \rightarrow \triangleright^\kappa A \rightarrow \triangleright^\kappa B.$$

Viewed as a function, \mathbf{ap}^κ takes $f : \triangleright^\kappa (A \rightarrow B)$ and $x : \triangleright^\kappa A$ as arguments, both of which are values that can be used in a next stage, and should produce a result of type $\triangleright^\kappa B$, that is, a value of type B in a next stage; this result is constructed by first taking in a tick α —after which the rest of the term describes a construction in the next stage—and then applying both f and x to α to produce $f[\alpha] : A \rightarrow B$, $x[\alpha] : A$, and eventually $f[\alpha] (x[\alpha]) : B$ in the next stage. Another important example is delaying a value to a next stage:

$$\mathbf{next}^\kappa \equiv \lambda x. \lambda \alpha. x : A \rightarrow \triangleright^\kappa A.$$

In contrast to \mathbf{next}^κ , there is no term of type $\triangleright^\kappa A \rightarrow A$, matching our intuition about a series of stages happening in order: in the current stage we should not be able to obtain a value that is only available in the next stage. Also there is no term of type $\triangleright^\kappa \triangleright^\kappa A \rightarrow \triangleright^\kappa A$ —it might be tempting to write $\lambda x. \lambda \alpha. x[\alpha][\alpha]$, but the two consecutive applications to α are prohibited in CCTT.

An important primitive is *guarded recursion*, also known as *Löb induction*: every function $f : \triangleright^\kappa A \rightarrow A$ has a delayed fixed point $\mathbf{dfix}^\kappa f : \triangleright^\kappa A$ with the fixed point equation $(\mathbf{dfix}^\kappa f)[\alpha] =_A f (\mathbf{dfix}^\kappa f)$ where the right-hand side can be seen as a fixed point of f without delay.

We now list some properties needed for Section 4.2.2. The first one helps to assure that we are still working with propositions and sets even when \triangleright^κ is involved.

► **Lemma 4.8.** *If $A[\alpha]$ is a proposition/set for arbitrary $\alpha : \kappa$, then so is $\triangleright(\alpha : \kappa). A[\alpha]$.*

The later modality distributes over a Σ -type.

► **Lemma 4.9.** *Let $B(x)$ be a family of types indexed by $x : A$. Then there are functions from $\triangleright^\kappa \sum_{(x:A)} B(x)$ to $\sum_{(x:\triangleright^\kappa A)} \triangleright(\alpha : \kappa). B(x[\alpha])$ and vice versa. In fact, the two types are equivalent.*

Therefore guarded recursion has a specialised form for Σ -types.

► **Corollary 4.10.** *Let $B(x)$ be a family of types indexed by $x : A$. Then*

$$\sum_{x:\triangleright^\kappa A} \triangleright(\alpha : \kappa). B(x[\alpha]) \rightarrow \sum_{x:A} B(x) \quad \text{implies} \quad \sum_{x:A} B(x).$$

The final property states that if two values delayed to a next stage are equal, then they are equal in the current stage. It may be tempting to formulate the property as $\mathbf{next}^\kappa x =_{\triangleright^\kappa A} \mathbf{next}^\kappa y \rightarrow x =_A y$, but this is in fact invalid, since (analogously to function extensionality) the antecedent equality is equivalent to $\triangleright^\kappa (x =_A y)$ rather than $x =_A y$ [18]. The correct formulation is the following, where the antecedent includes a *clock quantification* ‘ $\forall \kappa$ ’.

► **Lemma 4.11.** *Let x and $y : A$. Then $x =_A y$ if $\forall \kappa. \mathbf{next}^\kappa x =_{\triangleright^\kappa A} \mathbf{next}^\kappa y$.*

This lemma holds because, with clock quantification, it is possible to write Atkey and McBride's [3] operator $\text{force} : (\forall \kappa. \triangleright^\kappa A) \rightarrow (\forall \kappa. A)$, which can then be applied to the equality $\forall \kappa. \triangleright^\kappa (x =_A y)$ equivalent to the antecedent and yield $\forall \kappa. x =_A y$, which is equivalent to $x =_A y$. One way to think about (fully) clock-quantified types is that they are independent of the choice of clocks and can be viewed as the types of pure, completed descriptions of staged computation rather than ongoing computations that are taking effect in stages with respect to a particular clock in scope. We can manipulate such descriptions at will, irrespective of our current timeline—in particular, it is perfectly fine to take a description of a staged computation that produces results from the second stage onwards and make it produce the results right from the first stage instead, which is what force does.

4.2.2 Back to GL

First we adapt the definition of exposures to the setting of CCTT.

► **Definition 4.12** (Clocked exposure). Given \mathcal{P} -categories \mathbf{C} and \mathbf{D} , a *clocked exposure* $Q : \mathbf{C} \rightarrow \mathbf{D}$ consists of (a) a mapping Q^κ for each clock κ from objects X of \mathbf{C} to objects $Q^\kappa X$ of \mathbf{D} and (b) for each clock κ from well-defined morphisms $f : X \rightarrow Y$ to well-defined morphisms $Q^\kappa f : Q^\kappa X \rightarrow Q^\kappa Y$ satisfying following properties

- (i) $Q^\kappa \text{id}_X \sim \text{id}_{Q^\kappa X}$,
- (ii) $Q^\kappa (g \circ f) \sim Q^\kappa g \circ Q^\kappa f$, and
- (iii) $f \sim g$ whenever $\forall \kappa. Q^\kappa f \sim Q^\kappa g$ for any two well-defined morphisms $f, g : X \rightarrow Y$.

Notably, the faithfulness of a clocked exposure mirrors the form of Lemma 4.11, and is the main reason that we need CCTT.

Now we introduce the clocked exposure $\Box : \text{Asm}(\Lambda) \rightarrow \text{Asm}(\Lambda)$ modelling **GL**. For an assembly X , the carrier $|\Box^\kappa X|$ and the realisability relation $\Vdash_{\Box^\kappa X}$ are defined as

$$|\Box^\kappa X| := \sum_{(M:\Lambda_0)} \sum_{(x:\triangleright^\kappa |X|)} \triangleright(\alpha : \kappa). M \Vdash_X x[\alpha] \quad \text{and} \quad (N \Vdash_{\Box^\kappa X} (M, x, \star)) := N \twoheadrightarrow_\beta \ulcorner M \urcorner$$

where $\Vdash_{\Box^\kappa X}$ is defined in the same way as the exposure \Box . The main difference between the carriers $|\Box X|$ and $|\Box^\kappa X|$ is that the extension part $|X|$ becomes $\triangleright^\kappa |X|$. That is, the extension x is available in a next stage but not earlier (with respect to the clock κ), but the intension M remains the same type. Similarly, $\Box^\kappa X := (|\Box^\kappa X|, \Vdash_{\Box^\kappa X}, r_{\Box^\kappa X}, t_{\Box^\kappa X})$ is an assembly where $r_{\Box^\kappa X}$ and $t_{\Box^\kappa X}$ are given by the transitivity and the reflexivity of \twoheadrightarrow_β .

For any trackable map f from X to Y , also define $\Box^\kappa f$ in the same way as $\Box f$ except that a later modality is involved:

$$|\Box^\kappa f|(M, x, r) := (F[M], \triangleright^\kappa |f| x, \lambda \alpha. \mathfrak{f} M (x[\alpha]) (r[\alpha]))$$

where $\triangleright^\kappa |f| : \triangleright^\kappa |X| \rightarrow \triangleright^\kappa |Y|$ is given by the functoriality of the later modality \triangleright^κ . The very same argument for $\Box f$ shows that $\Box^\kappa f$ is indeed a trackable map from $|\Box^\kappa X|$ to $|\Box^\kappa Y|$.

► **Remark.** By Lemma 4.9, the carrier of $\Box^\kappa X$ and the type $\sum_{(M:\Lambda_0)} \triangleright^\kappa \sum_{(x:\triangleright^\kappa |X|)} M \Vdash_X x$ are interchangeable. The latter form is more convenient when using guarded recursion.

It is straightforward to show that \Box is a clocked exposure by Lemma 4.11.

► **Theorem 4.13.** $\Box : \text{Asm}(\Lambda) \rightarrow \text{Asm}(\Lambda)$ is a clocked exposure.

► **Proposition 4.14.** There is a family of trackable maps from $\Box^\kappa (X \Rightarrow Y)$ to $\Box^\kappa X \Rightarrow \Box^\kappa Y$ tracked by $\lambda x_0. \text{ap}[x_1] x_0$.

23:14 Realising Intensional S4 and GL Modalities

Similar to Theorem 4.7, no morphism $\Lambda_0 \rightarrow \Box^\kappa \Lambda_0$ can be quoting.

► **Theorem 4.15.** *There is no trackable map from Λ_0 to $\Box^\kappa \Lambda_0$ which quotes closed elements.*

It is also not possible to have a family of trackable maps ϵ_X from $\Box^\kappa X$ to X natural in X , since the extension of (M, x, r) can only be projected in a time step away from now.

► **Theorem 4.16.** *There is no function from $|\Box^\kappa \perp|$ to $|\perp|$. In particular, there is no natural transformation from \Box^κ to \mathcal{I} for any κ .*

Proof. Assume $\epsilon_\perp : |\Box^\kappa \perp| \rightarrow |\perp|$ exists. We show that there is **bang** : $\triangleright \mathbf{0} \rightarrow \mathbf{0}$, so by guarded recursion a contradiction $\text{fix } \text{bang} : \mathbf{0}$ is derivable. Let x be an inhabitant of $\triangleright \mathbf{0}$. We construct an inhabitant (M, x, r) of $\Box^\kappa \perp$ so that the function $|\epsilon_\perp|$ from $|\Box^\kappa \perp|$ to $|\perp| \equiv \mathbf{0}$ can be applied. Choose an arbitrary closed term M , say $\lambda x. x$, and apply the recursion principle $\text{rec}_\mathbf{0}$ of the empty type to x in a time step to get $r := \lambda \alpha. \text{rec}_\mathbf{0} (M \Vdash_\perp x[\alpha]) x[\alpha]$, which is an inhabitant of $\triangleright(\alpha : \kappa). M \Vdash_\perp x[\alpha]$, so (M, x, r) is of type $|\Box^\kappa \perp|$. ◀

The pay-off for disallowing evaluation is to be able to derive intensional recursion, which is logically the deductive form(s) of the Gödel-Löb axiom, as well as the **GL** axiom.

► **Theorem 4.17** (Intensional recursion). *For every trackable map $f : \Box^\kappa X \rightarrow X$, there are*
 1. *an element f^\dagger of $\Box^\kappa X$ tracked by $\ulcorner \text{fix } F \urcorner$, and*
 2. *an element f^\ddagger of X tracked by $\text{fix } F$ with $f^\ddagger \sim f \circ \Box^\kappa f^\ddagger \circ \star$*
where $\text{fix } F : \Lambda_0$ satisfies $\text{fix } F \longrightarrow_\beta F[\ulcorner \text{fix } F \urcorner]$.

Proof. Let f be a trackable map from $\Box^\kappa X$ to X tracked by $F : \Lambda_1$. Applying Theorem 2.2 to $\lambda x_0. F : \Lambda_0$, we obtain a term $\text{fix } F : \Lambda_0$ with $\text{fix } F \longrightarrow_\beta (\lambda x_0. F) \ulcorner \text{fix } F \urcorner \longrightarrow_\beta F[\ulcorner \text{fix } F \urcorner]$. Now we construct the first element by Löb induction on a Σ -type (Corollary 4.10): assuming

$$x : \triangleright |X| \quad \text{and} \quad r : \triangleright(\alpha : \kappa). F[\ulcorner \text{fix } F \urcorner] \Vdash x[\alpha]$$

we show an inhabitant of type $|X|$ realised by $\ulcorner \text{fix } F \urcorner$ as follows.

1. First, $\triangleright(\alpha : \kappa). (\text{fix } F \Vdash x[\alpha])$ has an inhabitant, say r' , since $\text{fix } F$ reduces to $F[\ulcorner \text{fix } F \urcorner]$.
2. Then, we derive an inhabitant of type $|X|$ realised by $F[\ulcorner \text{fix } F \urcorner]$ as witnessed by

$$f(\text{refl}_{\longrightarrow} \ulcorner \text{fix } F \urcorner) : F[\ulcorner \text{fix } F \urcorner] \Vdash |f|(\text{fix } F, x, r')$$

since F tracks $|f|$ and the set $\ulcorner \text{fix } F \urcorner \Vdash_{\Box^\kappa X} (\text{fix } F, x, r')$ is judgementally equal to $\ulcorner \text{fix } F \urcorner \longrightarrow_\beta \ulcorner \text{fix } F \urcorner$, which is inhabited by $\text{refl}_{\longrightarrow}$.

3. By Löb induction, $\sum_{(x : \triangleright |X|)} \triangleright(\alpha : \kappa). F[\ulcorner \text{fix } F \urcorner] \Vdash x[\alpha]$ has an inhabitant (x_0, r_0) .
4. By $\text{fix } F \longrightarrow_\beta F[\ulcorner \text{fix } F \urcorner]$, we have $(\text{fix } F, x_0, r'_0) : |\Box^\kappa X|$ where $r'_0 : \triangleright(\alpha : \kappa). \text{fix } F \Vdash x_0[\alpha]$. Clearly $(\text{fix } F, x_0, r'_0)$ is realised by $\ulcorner \text{fix } F \urcorner$, and by Lemma 3.8 it gives an element f^\dagger of $\Box^\kappa X$.

To construct the second element f^\ddagger , we follow the same steps except the third: we conclude $(x_0, r_0) : \sum_{(x : |X|)} F[\ulcorner \text{fix } F \urcorner] \Vdash x[\alpha]$ without any delay and thus $x_0 : |X|$ is realised by $r'_0 : \text{fix } F \Vdash x_0$. The equation $f^\ddagger \sim f \circ \Box^\kappa (f^\ddagger) \circ \star$ follows from the fixed point equation for guarded recursion. ◀

The **GL** axiom can be realised by a similar construction, too.

► **Theorem 4.18.** *There is a family of trackable maps from $\Box^\kappa(\Box^\kappa X \Rightarrow X)$ to $\Box^\kappa X$.*

5 Related work

Kavvos introduced a comonadic exposure [14, Theorem 11], which we denote by \boxtimes_K here, on \mathcal{P} -category of assemblies on a PCA (instead of λ -calculus) to model the intensional **S4** modality. For an assembly X on a PCA (A, \cdot) , the assembly $\boxtimes_K X$ is defined by

$$|\boxtimes_K X| \equiv \{ (a, x) \mid a \Vdash x \} \quad \text{and} \quad b \Vdash_{\boxtimes_K X} (a, x) \equiv a = b,$$

without the use of Gödel encoding. The mapping on morphisms is similar to \boxtimes . Besides the use of set theory as the metalanguage for the development, the exposure \boxtimes_K differs from \boxtimes in many ways. First, the exposure \boxtimes_K preserves finite products, while \boxtimes does not. Some β -equivalent intensions have to be identified to satisfy equations of PCA. For example $\star : |\top|$ has only one realiser \mathbf{I} , so $|\boxtimes_K \top|$ has only one element (\star, \mathbf{I}) , too. Second, \boxtimes_K is comonadic by a similar reason, while our δ is not even natural. Third, \boxtimes_K is idempotent, i.e. δ are isomorphisms, which is impossible for \boxtimes because of Gödel encoding. Finally, it is not clear how to refute the generic quoting for \boxtimes_K . Using λ -terms subject to α -equivalence as realisers and $\ulcorner M \urcorner$ as realisers for (M, x, r) , the exposure \boxtimes is able to distinguish β -equivalent intensions, so \boxtimes —being more intensional than \boxtimes_K —lacks well-behaved extensional properties.

Artemov and Beklemishev [2] pointed out that Gödel attempted to use classical **S4** modal logic to capture provability for Peano Arithmetic (**PA**) but realised that $\text{Prov}(A) \equiv \exists x. \text{Proof}(x, A)$ cannot be **S4**. Löb found the well-known **GL** axiom and Solovay showed that **GL** is complete with respect to **PA**. On the other hand, Artemov [1] proposed *logic of proofs* extending **S4** and argued that **S4** is for *explicit proofs*. Goris [11] discussed two modalities **GL** and **S4** over classical logic by presenting a bi-modal logic and provides a Kripke semantics for both. We took Goris' notation for the **S4** modality \boxtimes . Our work is partly inspired by Shamkanov's [23, 24] provability semantics for **GL** using circular proofs.

6 Conclusion

In this paper we follow the principle of modality-as-intension [8] and the \mathcal{P} -categorical semantics [14] to manifest the concepts of denotations, extensions, and intensions. We have studied the \mathcal{P} -category of assemblies on λ -calculus developed and formalised in HoTT as a semantic foundation for intensionality, on which we modelled **S4** and **GL** modalities. Notably, our denotational semantics of the **S4** modality \boxtimes is more intensional than that of Kavvos' \boxtimes_K . For the **GL** modality \square , we have given the *first* denotational semantics, which is shown (Theorem 4.17 and Theorem 4.18) to satisfy the Gödel-Löb axiom and its deductive form—the intensional recursion—using guarded type theory.

As future work, an important issue we have not discussed yet is the connection between \boxtimes and \square —for example, it is easy to construct a family of trackable maps from $\boxtimes X$ to $\square^* X$ natural in X by deferring the extension part of (M, x) to a later stage, and Goris' bi-modal logic [11] suggests that there are more rules to discover. In the long term, based on the \mathcal{P} -category of assemblies and the denotational semantics of modalities, we intend to design a type theory with two modes of **Code** and prove its meta-properties such as consistency, confluence, and decidability of type checking by interpreting judgements into $\text{Asm}(\Lambda)$.
